**ABSTRACT**

The mineral geminite, an hydrated hydroxy-arsenate mineral of formula Cu(AsO<sub>3</sub>OH)·H<sub>2</sub>O, has been studied by Raman and infrared spectroscopy. Two minerals from different origins were investigated and the spectra proved quite similar. In the Raman spectra of geminite, four bands are observed at 813, 843, 853 and 885 cm<sup>-1</sup>. The assignment of these bands is as follows: (a) The band at 853 cm<sup>-1</sup> is assigned to the AsO<sub>4</sub><sup>3-</sup> ν<sub>1</sub> symmetric stretching mode (b) the band at 885 cm<sup>-1</sup> is assigned to the AsO<sub>3</sub>OH<sup>2-</sup> ν<sub>1</sub> symmetric stretching mode (c) the band at 843 cm<sup>-1</sup> is assigned to the AsO<sub>4</sub><sup>3-</sup> ν<sub>3</sub> antisymmetric stretching mode (d) the band at 813 cm<sup>-1</sup> is ascribed to the AsO<sub>3</sub>OH<sup>2-</sup> ν<sub>3</sub> antisymmetric stretching mode. Two Raman bands at 333 and 345 cm<sup>-1</sup> are attributed to the ν<sub>2</sub> AsO<sub>4</sub><sup>3-</sup> bending mode and a set of higher wavenumber bands are assigned to the ν<sub>4</sub> AsO<sub>4</sub><sup>3-</sup> bending mode. A very complex set of overlapping bands is observed in both the Raman and infrared spectra. Raman bands are observed at 2288, 2438, 2814, 3152, 3314, 3448 and 3521 cm<sup>-1</sup>. Two Raman bands at 2288 and 2438 cm<sup>-1</sup> are ascribed to very strongly hydrogen bonded water. The broader Raman bands at 3152 and 3314 cm<sup>-1</sup> may be assigned to adsorbed water and not so strongly hydrogen bonded water in the molecular structure of geminate. Two bands at 3448 and 3521 cm<sup>-1</sup> are assigned to the OH stretching vibrations of the (AsO<sub>3</sub>OH)<sup>2-</sup> units. Raman spectroscopy identified Raman bands attributable to AsO<sub>4</sub><sup>3-</sup> and AsO<sub>3</sub>OH<sup>2-</sup> units.

**KEYWORDS:** geminite, acid-arsenate, arsenate, Raman spectroscopy

## INTRODUCTION

Geminite <sup>1-4</sup> Cu(AsO<sub>3</sub>OH)·H<sub>2</sub>O is an acid arsenate with a triclinic structure normally found in the deposits of arsenic bearing Cu-Pb deposits. The structure of geminate has been published by Cooper and Hawthorne <sup>2</sup>. However to the best of our knowledge no vibrational spectroscopy of this mineral has been published. According to Cooper and Hawthorne, in the structure of geminate, there are four unique Cu<sup>2+</sup> sites, each coordinated by six anions in a [4 + 2]-distorted octahedral arrangement <sup>2</sup>. There are four unique As<sup>5+</sup> sites, each coordinated by three oxygen atoms and an OH group in a distorted tetrahedral arrangement. The three As-O distances are shorter than the As-OH distance in each tetrahedron, in according to the prediction of bond-valence theory <sup>2</sup>. The copper polyhedra share edges to form chains parallel to [010]; As.vphi.4 tetrahedra cross-link these chains into sheets parallel to (001), and there are two symmetrical distinct but topologically identical sheets in the structure. These sheets are linked into a three-dimensional structure by a network of H bonds, accounting for the perfect cleavage and platy habit of geminite.

The aim of this paper is to report the Raman spectra of geminite, and to relate the spectra to the molecular and crystal chemistry of this arsenate type mineral. The paper follows the systematic research on Raman and infrared spectroscopy of secondary minerals containing oxy-anions formed in the oxidation zone <sup>5-16</sup>.

## EXPERIMENTAL

### Minerals

The mineral geminite originated from the Jáchymov (St Joachimsthal), Ostrov, Krusné Hory Mountains (Erzgebirge), Karlovy Vary Region, Bohemia (Böhmen; Boehmen), Czech Republic. A second sample was obtained from the cap Garonne Mine, France <sup>4</sup>. The chemical analysis of the geminite can be found in Anthony et al. (page 212) <sup>17</sup>.the crystal structure of this mineral has been published <sup>2</sup>.

### Raman spectroscopy

Crystals and single crystal samples of geminite were placed on a polished metal surface on the stage of an Olympus BHSM microscope, which is equipped with 10x, 20x, and 50x objectives. The microscope is part of a Renishaw 1000 Raman microscope system, which also includes a monochromator, a filter system and a CCD detector (1024 pixels). The Raman spectra were excited by a Spectra-Physics model 127 He-Ne laser producing highly polarised light at 633 nm and collected at a nominal resolution of  $2\text{ cm}^{-1}$  and a precision of  $\pm 1\text{ cm}^{-1}$  in the range between 200 and  $4000\text{ cm}^{-1}$ . Repeated acquisition on the crystals using the highest magnification (50x) were accumulated to improve the signal to noise ratio in the spectra. Spectra were calibrated using the  $520.5\text{ cm}^{-1}$  line of a silicon wafer. Previous studies by the authors provide more details of the experimental technique. Alignment of all crystals in a similar orientation has been attempted and achieved. However, differences in intensity may be observed due to minor differences in the crystal orientation<sup>9-16, 18-25</sup>.

## **Infrared spectroscopy**

Infrared spectra of dussertite sample were recorded by micro diffuse reflectance method (DRIFTS) on a Nicolet Magna 760 FTIR spectrometer (range  $4000\text{-}600\text{ cm}^{-1}$ , resolution  $4\text{ cm}^{-1}$ , 128 scans, 2 level zero-filtering, Happ-Genzel apodization), equipped with Spectra Tech InspectIR micro FTIR accessory. Each sample of amount less than 0.050 mg was mixed without using pressure with KBr. Samples were immediately recorded together with the same KBr as a reference.

Spectral manipulation such as baseline correction/adjustment and smoothing were performed using the Spectralcalc software package GRAMS (Galactic Industries Corporation, NH, USA). Band component analysis was undertaken using the Jandel 'Peakfit' software package that enabled the type of fitting function to be selected and allows specific parameters to be fixed or varied accordingly. Band fitting was done using a Lorentzian-Gaussian cross-product function with the minimum number of component bands used for the fitting process. The Gaussian-Lorentzian ratio was maintained at values greater than 0.7 and fitting was undertaken until reproducible results were obtained with squared correlations of  $r^2$  greater than 0.995.

## RESULTS AND DISCUSSION

### Arsenate vibrations

The free arsenate ion has tetrahedral symmetry and thus should have four bands of which two are infrared active with theoretical values of  $\nu_3$  ( $F_2$ )  $887\text{ cm}^{-1}$  and  $\nu_4$  ( $F_2$ )  $463\text{ cm}^{-1}$ . The Raman active modes are observed at  $837$  ( $A_1$ ) and  $349$  ( $E$ )  $\text{cm}^{-1}$ . Upon coordination of the arsenate ion to the copper atom, then the symmetry of the arsenate ion reduces to  $C_{3v}$  and may further reduce to  $C_{2v}$ . The implication is that all bands will be both infrared and Raman active. The Raman spectra of the tetrahedral anions in aqueous systems are well known. The symmetric stretching vibration of the arsenate anion ( $\nu_1$ ) is observed at  $810\text{ cm}^{-1}$  and coincides with the position of the asymmetric stretching mode ( $\nu_3$ ). The symmetric bending mode ( $\nu_2$ ) is observed at  $342\text{ cm}^{-1}$  and the out-of-plane bending modes ( $\nu_4$ ) is observed at  $398\text{ cm}^{-1}$ . Of all the tetrahedral oxyanions spectra, the positions of the arsenate vibrations occur at lower wavenumbers than any of the other naturally occurring mineral oxyanions spectra. Farmer lists a number of spectra of arsenates including the basic copper arsenates olivenite and euchroite.<sup>26</sup> The effect of the arsenate ion in a crystal will be to remove the degeneracy and allow splitting of the bands according to factor group analysis. The  $\nu_1$  and  $\nu_3$  infrared bands of olivenite and euchroite were observed at  $860, 828, 790\text{ cm}^{-1}$  and  $830$  and  $770\text{ cm}^{-1}$  respectively. The bending modes were found at  $493$  and  $452\text{ cm}^{-1}$  for olivenite and at  $475$  and  $410\text{ cm}^{-1}$  for euchroite. No  $\nu_2$  bands were shown. This is no doubt related to the fact the bands are found below  $400\text{ cm}^{-1}$ , which makes the measurement by infrared spectroscopy difficult. Two OH stretching vibrations were observed at  $3580$  and  $3440\text{ cm}^{-1}$  for olivenite. A number of bands were listed which were unassigned.

### Raman spectroscopy of geminite

According to Myneni *et al.*<sup>27,28</sup> and Nakamoto<sup>29</sup>,  $(\text{AsO}_4)^{3-}$  is a tetrahedral unit, which exhibits four fundamental vibrations: the  $\nu_1$  symmetric stretching vibration ( $A_1$ )  $818\text{ cm}^{-1}$ , Raman active; the doubly degenerate  $\nu_2$  symmetric bending vibration ( $E$ )  $350\text{ cm}^{-1}$ , Raman active; the triply degenerate  $\nu_3$  antisymmetric stretching vibration ( $F_2$ )  $786\text{ cm}^{-1}$ , and the triply degenerate  $\nu_4$  bending vibration ( $F_2$ )  $405\text{ cm}^{-1}$ , both infrared and Raman active. Protonation, metal complexation, and/or adsorption on a mineral surface should cause change

in  $(\text{AsO}_4)^{3-}$  symmetry from  $T_d$  to lower symmetries, such as  $C_{3v}$ ,  $C_{2v}$  or  $C_1$ . This loss of degeneracy causes splitting of degenerate vibrations of  $(\text{AsO}_4)^{3-}$  and the shifting of the As-OH stretching vibrations to different wavenumbers. Such chemical interactions reduce  $(\text{AsO}_4)^{3-}$  tetrahedral symmetry, as mentioned above, to either  $C_{3v}/C_3$  (corner-sharing),  $C_{2v}/C_2$  (edge-sharing, bidentate binuclear), or  $C_1/C_s$  (corner-sharing, edge-sharing, bidentate binuclear, multidentate)<sup>27,28</sup>. In association with  $(\text{AsO}_4)^{3-}$  symmetry and coordination changes, the  $A_1$  band may shift to different wavenumbers and the doubly degenerate E and triply degenerate F modes may give rise to several new  $A_1$ ,  $B_1$ , and/or  $E$  vibrations<sup>27,28</sup>. In the absence of symmetry deviations,  $(\text{AsO}_3\text{OH})^{2-}$  in  $C_{3v}$  symmetry exhibit the  $\nu_s$  As-OH and  $\nu_{as}$  and  $\nu_s$   $(\text{AsO}_3\text{OH})^{2-}$  vibrations together with corresponding the  $\delta$  As-OH in-plane bending vibration,  $\delta$  As-OH out-of-plane bending vibration,  $\nu_s$   $(\text{AsO}_3\text{OH})^{2-}$  stretching vibration and  $\delta_{as}$   $(\text{AsO}_3\text{OH})^{2-}$  bending vibration<sup>30-32</sup>. Keller<sup>30</sup> assigned observed the following infrared bands in  $\text{Na}_2(\text{AsO}_3\text{OH}) \cdot 7\text{H}_2\text{O}$  450 and 360  $\text{cm}^{-1}$  to the  $\delta_{as}$  ( $\nu_4$ )  $(\text{AsO}_3\text{OH})^{2-}$  bend ( $E$ ), 580  $\text{cm}^{-1}$  to the  $\delta$  As-OH out-of-plane bend, 715  $\text{cm}^{-1}$  to the  $\nu$  As-OH stretch ( $A_1$ ), 830  $\text{cm}^{-1}$  to the  $\nu_{as}$   $(\text{AsO}_3\text{OH})^{2-}$  stretch ( $E$ ), and 1165  $\text{cm}^{-1}$  to the  $\delta$  As-OH in plane bend. In the Raman spectrum of  $\text{Na}_2(\text{AsO}_3\text{OH}) \cdot 7\text{H}_2\text{O}$ , Vansant *et al.*<sup>31</sup> attributed observed Raman bands to the following vibrations 55, 94, 116 and 155  $\text{cm}^{-1}$  to lattice modes, 210  $\text{cm}^{-1}$  to  $\nu$  (OH...O) stretch, 315  $\text{cm}^{-1}$  to  $(\text{AsO}_3\text{OH})^{2-}$  rocking, 338  $\text{cm}^{-1}$  to the  $\delta_s$   $(\text{AsO}_3)^{2-}$  bend, 381  $\text{cm}^{-1}$  to the  $\delta_{as}$   $(\text{AsO}_3\text{OH})^{2-}$  bend, 737  $\text{cm}^{-1}$  to the  $\nu_s$  As-OH stretch ( $A_1$ ), 866  $\text{cm}^{-1}$  to the  $\nu_{as}$   $(\text{AsO}_3\text{OH})^{2-}$  stretch ( $E$ ).

The Raman spectra of the mineral geminite from Jáchymov, The Czech Republic, in the 650 to 1000  $\text{cm}^{-1}$  region are displayed in Fig. 1. In the spectral region from 750 to 950  $\text{cm}^{-1}$  a complex set of overlapping bands is observed. Four bands are observed at 813, 843, 853 and 885  $\text{cm}^{-1}$ . The assignment of these bands is as follows: (a) The band at 853  $\text{cm}^{-1}$  is assigned to the  $\text{AsO}_4^{3-}$   $\nu_1$  symmetric stretching mode (b) the band at 885  $\text{cm}^{-1}$  is assigned to the  $\text{AsO}_3\text{OH}^{2-}$   $\nu_1$  symmetric stretching mode (c) the band at 843  $\text{cm}^{-1}$  is assigned to the  $\text{AsO}_4^{3-}$   $\nu_3$  antisymmetric stretching mode (d) the band at 813  $\text{cm}^{-1}$  is ascribed to the  $\text{AsO}_3\text{OH}^{2-}$   $\nu_3$  antisymmetric stretching mode.

The infrared spectrum of geminate from (a) France and (b) Jáchymov, The Czech Republic in the 600 to 1000  $\text{cm}^{-1}$  region is shown in Fig. 2. The infrared spectrum complements the Raman spectrum. The infrared spectrum exhibits a complex set of overlapping bands. Remarkable similarity exists for the two spectra from geminate samples

from two different origins. Infrared bands are found at 740, 760, 804, 830, 850 and 877  $\text{cm}^{-1}$ . The two infrared bands at 850 and 877  $\text{cm}^{-1}$  seem to correspond with the Raman bands at 853 and 885  $\text{cm}^{-1}$  assigned to the  $\text{AsO}_4^{3-}$   $\nu_1$  symmetric stretching mode and the  $\text{AsO}_3\text{OH}^{2-}$   $\nu_1$  symmetric stretching mode respectively.

In the Raman spectrum, a band at 743  $\text{cm}^{-1}$  is observed and is assigned to an OH deformation mode. Distinct infrared bands are also observed at 739  $\text{cm}^{-1}$  (France) and 740  $\text{cm}^{-1}$  (Jácymov). These bands are also attributed to the OH deformation mode. The Raman spectra of geminite in the 100 to 600  $\text{cm}^{-1}$  region are displayed in Fig. 3. Raman bands are observed at 333, 345, 421, 451, 481 and 479  $\text{cm}^{-1}$ . The two bands at 333 and 345  $\text{cm}^{-1}$  are attributed to the  $\nu_2$   $\text{AsO}_4^{3-}$  bending mode. The set of higher wavenumber bands are assigned to the  $\nu_4$   $\text{AsO}_4^{3-}$  bending mode. Intense Raman bands are observed on the far low wavenumber region at 136, 161, and 182  $\text{cm}^{-1}$ . It is considered that these bands are related to hydrogen bonding of the water molecule in the geminate structure. Other low intensity bands are observed at 213, 244, 284 and 310  $\text{cm}^{-1}$ . It is suggested that these bands are related to CuO stretching and bending bands.

The Raman spectrum of geminate from 1000 to 3600  $\text{cm}^{-1}$  is displayed in Fig. 4. In the higher wavenumber region of the Czech sample, Raman bands are observed at 2288, 2438, 2814, 3152, 3314, 3448 and 3521  $\text{cm}^{-1}$ . For the geminite sample from France, Raman bands are observed at 2289, 2433, 2737, 2855, 3525, 3305, 3377, 3449 and 3521  $\text{cm}^{-1}$ . There is good correspondence between the Raman spectra of the two geminite samples.

What this spectrum does is describe water in different molecular environments. The two Raman bands at around 2288 and 2438  $\text{cm}^{-1}$  are ascribed to very strongly hydrogen bonded water. The broader Raman bands at 3152 and 3314  $\text{cm}^{-1}$  may be assigned to adsorbed water and not so strongly hydrogen bonded water in the molecular structure of geminate. The two bands at 3448 and 3521  $\text{cm}^{-1}$  are assigned to the OH stretching vibrations of the  $(\text{AsO}_3\text{OH})^{2-}$  units. The infrared spectra of geminate in the 1000 to 4000  $\text{cm}^{-1}$  are displayed in Fig. 5. Infrared bands are found in similar positions to those shown in the Raman spectrum. Importantly two infrared bands are observed at 1631 and 1670  $\text{cm}^{-1}$  (France) and 1632 and 1689  $\text{cm}^{-1}$  (Czech). These two bands are assigned to water HOH bending modes. The fact that two bands are observed provides good evidence for two different types of water molecules in the geminate structure. One water molecule is water

involved in very strongly hydrogen bonding and is reflected in the bending mode at  $\sim 1689$   $\text{cm}^{-1}$ ; the second is more weakly hydrogen bonding and is reflected in the water bending mode at  $1632$   $\text{cm}^{-1}$ . These bands are associated with the OH stretching vibrations. The water OH stretching bands at  $2337$ ,  $2403$  and  $2469$   $\text{cm}^{-1}$  (France) and  $2268$ ,  $2396$  and  $2452$   $\text{cm}^{-1}$  (Czech) are attributed to very strongly hydrogen bonded water. The broader infrared bands at  $2820$ ,  $3037$ ,  $3190$  and  $3311$   $\text{cm}^{-1}$  (France) and  $2763$ ,  $2966$ ,  $3176$ ,  $3305$ ,  $3330$  and  $3454$   $\text{cm}^{-1}$  (Czech) are assigned to the more weakly hydrogen bonded water molecules. The two infrared bands at  $3452$  and  $3520$   $\text{cm}^{-1}$  (France) and  $3520$  and  $3565$   $\text{cm}^{-1}$  (Czech) are assigned to the OH stretching bands of the OH units of  $(\text{AsO}_3\text{OH})^{2-}$  units.

## CONCLUSIONS

The Raman and infrared spectra of geminite from Jáchymov, Czech Republic and cap, Garonne Mine, France were obtained and related to the structure of the mineral. Raman bands attributable to the stretching and bending vibrations of the  $(\text{AsO}_4)^{3-}$  and  $(\text{AsO}_3\text{OH})^{2-}$  units are obtained. Well defined OH stretching bands are found as well as bands attributable to adsorbed water. The Raman spectrum shows a complex set of overlapping bands in the OH stretching region. It is proposed that the OH units in the geminite structure are non-equivalent. A complex set of overlapping bands are observed in the OH stretching region. Raman bands are assigned to very strongly hydrogen bonded water molecules and to less strongly hydrogen bonded water. Raman bands are attributed to the OH stretching vibrations of the  $(\text{AsO}_3\text{OH})$  units. Corresponding bands are observed in the infrared spectra.
