## Correlates of Sitting Time in Working Age Australian Women: Who Should Be Targeted With Interventions to Decrease Sitting Time?

Jannique G. Z. van Uffelen, Kristiann C. Heesch, and Wendy Brown

**Background:** While there is emerging evidence that sedentary behavior is negatively associated with health risk, research on the correlates of sitting time in adults is scarce. **Methods:** Self-report data from 7724 women born between 1973–1978 and 8198 women born between 1946–1951 were collected as part of the Australian Longitudinal Study on Women’s Health. Linear regression models were computed to examine whether demographic, family and caring duties, time use, health, and health behavior variables were associated with weekday sitting time. **Results:** Mean sitting time (SD) was 6.60 (3.32) hours/day for the 1973–1978 cohort and 5.70 (3.04) hours/day for the 1946–1951 cohort. Indicators of socioeconomic advantage, such as full-time work and skilled occupations in both cohorts and university education in the mid-age cohort, were associated with high sitting time. A cluster of ‘healthy behaviors’ was associated with lower sitting time in the mid-aged women (moderate/high physical activity levels, nonsmoking, nondrinking). For both cohorts, sitting time was highest in women in full-time work, in skilled occupations, and in those who spent the most time in passive leisure. **Conclusions:** The results suggest that, in young and mid-aged women, interventions for reducing sitting time should focus on both occupational and leisure-time sitting.

**Keywords:** sedentary behavior, lifestyle, observational study, socioeconomic factors, health behaviors

In epidemiological studies of physical activity (PA) and health, people are often categorized as ‘active’ (meeting a PA guideline), ‘inactive’ (reporting some PA but not meeting the guideline), or ‘sedentary’ (reporting no PA), based on responses to questions about their participation in moderate and vigorous physical activity (MVPA). In this context, sedentary behavior is conceptualized as a lack of MVPA. However, in recent years the term ‘sedentary behavior’ has been used to describe participation in activities requiring low energy expenditure, such as sitting or lying down, regardless of participation in MVPA.<sup>1,2</sup>

There is a rapidly growing body of evidence suggesting that more time spent in sedentary behaviors, independent of MVPA levels, is associated with increased health risk.<sup>3–8</sup> Cross-sectional studies in Australia, the US, and the UK have shown positive associations between increased TV time and body mass index (BMI),<sup>5,6,8</sup> blood pressure,<sup>5,8</sup> fasting insulin,<sup>8</sup> and breast density (a marker of breast cancer risk).<sup>9</sup> Prospective studies have also shown associations between sitting time and obesity,<sup>3,4,10,11</sup> biomarkers of cardiovascular disease risk,<sup>11</sup> and mortality.<sup>12,13</sup>

Researchers are beginning to explore the feasibility and efficacy of interventions to reduce sitting time. Understanding the correlates of sitting time is vital for informing the development of these interventions and for identifying which population subgroups are most sedentary and thus most likely to benefit from interventions. To date, studies of the correlates of sitting time in adults have predominantly focused on TV viewing. Australian, US, and Scottish studies have shown that high TV time is associated with low socioeconomic status (eg, living in a deprived neighborhood,<sup>14,15</sup> low education levels,<sup>16,17</sup> low income<sup>14–16</sup>), other demographic characteristics (eg, being female,<sup>17</sup> older age,<sup>16,17</sup> no paid job<sup>16,17</sup>), and health risk factors (eg, low PA levels,<sup>17</sup> high energy intake,<sup>16</sup> overweight or obese<sup>14,16,17</sup>). However, in focusing only on TV viewing, these studies have not considered time spent sitting in other domains, such as transport and work. This is important because data from The Netherlands and Australia indicate that working adults spend about one-half to one-third of their workday sitting.<sup>18,19</sup>

The Australian Longitudinal Study on Women’s Health (ALSWH) provides an opportunity to examine the correlates of sitting time, including sitting for leisure, during transport, and at work, in national samples of working age women. The aim of this study was to identify correlates of weekday sitting time in the ALSWH 1973–1978 and 1946–1951 cohorts. Demographic characteristics, family and caring duties and time use, as well

as health and health behavior variables, were considered as potential correlates.

## Methods

### Australian Longitudinal Study on Women's Health

The ALSWH is a prospective study of factors affecting the health and well-being of 3 cohorts of Australian women (born in 1973–1978, in 1946–1951, and in 1921–1926),<sup>20</sup> randomly selected from the national health insurance database,<sup>21</sup> with oversampling of women from rural and remote areas. More details about the study can be found at [www.alswh.org.au](http://www.alswh.org.au). The study was approved by the University of Queensland and the University of Newcastle Ethics Committees, and written informed consent was received from all respondents.

### Study Sample

These analyses used data collected from the 2003 survey of women born in 1973–1978 (when they were age 25–30 years old) and the 2001 survey of women born in 1946–1951 (when they were age 50–55 years old). These were the first surveys to assess sitting time in both cohorts. Women born between 1921–1926 were not included because they had reached retirement age before their first survey.

The first ALSWH survey in 1996 was completed by 14,739 women in the 1973–1978 cohort and 14,099 women in the 1946–1951 cohort. These women were broadly representative of the general population in their age groups,<sup>20</sup> although there was over-representation of Australian-born, employed, and university-educated women.<sup>21</sup> After losing women to follow-up, the third survey was completed by 9081 women in the 1973–1978 cohort and 11,200 women in the 1946–1951 cohort. Of these women, those who reported a limited ability to walk 100 m were excluded to ensure that women included in the analyses were not sitting because they were wheelchair-bound ( $n = 161$  for 1973–1978 cohort;  $n = 182$  for 1946–1951 cohort), leaving data from 8920 women in the 1973–1978 cohort and 11,018 women in the 1946–1951 cohort available for inclusion in these analyses.

### Measures

**Sitting Time.** The following question was used to assess sitting time: How many hours each day do you typically spend sitting down while doing things like visiting friends, driving, reading, watching television or working at a desk or computer on a usual weekday? Established protocols were used to clean the data and values exceeding 16 hours/day were set to missing.<sup>22</sup> The question is similar to the one included in the International PA Questionnaire, which, in women, has been shown to have good reliability and moderate criterion validity against accelerometers (<100 counts per minute).<sup>23</sup>

**Potential Correlates of Sitting Time.** Variables hypothesized to be associated with sitting time included demographic characteristics, family and caring duties, time use, health, and health behavior variables. Variables were categorized as shown in Table 1.

Demographic variables included area of residence (derived from postal code), country of birth, highest level of education, income management, and occupation (from the Australian Standard Coding of Occupations<sup>24</sup>). Income management was assessed in ALSWH as a proxy for income status, because some women were reticent to report their actual income. Occupation was categorized as professional (manager, administrator), skilled (tradesperson, advanced clerical, or service worker), blue collar (laborer, production/transport worker, elementary/intermediate sales/service worker), or no paid job.

Women were asked about their marital status and their caring duties for people with a long-term illness, disability, or frailty. Women in the 1973–1978 cohort were also asked for the number of children they had and their pregnancy status. Women in the 1946–1951 cohort were also asked to report the frequency of providing care for grandchildren.

Women reported the hours they spent in the previous week in paid work (full-time, part-time, casual), doing home duties (own/family home), studying, and in passive leisure (eg, TV, listening to music, reading, relaxing).

BMI was calculated as  $\text{kg/m}^2$  based on self-reported weight and height, and categorized in accordance with the World Health Organization classification.<sup>25</sup> Number of chronic diseases was derived from a list of health conditions, including diabetes, cancer, and heart disease, that women reported they had been told they had by a doctor in the previous 3 years.<sup>26</sup> They also reported whether they had sleeping problems or stiff or painful joints in the last 12 months.

The questions to assess PA were adapted from Active Australia questions, which have acceptable measurement characteristics.<sup>27</sup> They ask about walking, moderate-intensity, and vigorous-intensity physical activities in the last week. As reported previously,<sup>28</sup> responses were used to derive a PA score, which was categorized as shown in Table 1.

Energy intake (EI) was assessed using the Cancer Council of Victoria food frequency questionnaire.<sup>29</sup> EI was computed as described previously<sup>30</sup> and quintiles of EI were used in the analysis. Smoking and alcohol status were derived from standard questions.

### Statistical Analysis

Linear regression modeling was used to examine the associations between potential correlates of sitting time (all categorical variables), and sitting time (continuous, normally distributed variable). First, separately for each cohort, univariate models were computed to examine associations between each potential correlate and sitting time. Variables that were significantly associated with sitting time were next included in a multivariable

<sup>d</sup> Very low (≤4800 KJ for both cohorts), low (>4800 to 6000 KJ in 1973–1978 cohort; >4800 to 5800 KJ in 1946–1951 cohort), moderate (>6000 to 7100 KJ in 1973–1978 cohort; >5800 to 6800 KJ in 1946–1951 cohort), high (7100–8800 KJ in 1973–1978 cohort; >6800 to 8300 KJ in 1946–1951 cohort), and very high (>8800 KJ in 1973–1978 cohort; >8300 KJ in 1946–1951 cohort).

model (one model for each cohort). The analyses were conducted using SPSS V16.0. Statistical significance was set at  $P \leq .05$ .

## Results

Of the 8920 women in the 1973–1978 cohort and the 11,018 women in the 1946–1951 cohort who were eligible for the study, women were excluded if they had missing sitting time data ( $n = 364$  for 1973–1978 cohort;  $n = 710$  for 1946–1951 cohort) or missing data for any potential correlate ( $n = 832$  for 1973–1978 cohort;  $n = 2110$  for 1946–1951 cohort). The percentage of missing data were  $< 5\%$  for each potential correlate. The analysis sample was thus 7724 and 8198 for the 1973–1978 cohort and 1946–1951 cohort, respectively. The women who were included in the analysis had higher socioeconomic status, had fewer health problems, and engaged in more healthy behaviors than those excluded, although differences were small (Appendix Tables 1 and 2). Characteristics of the women included in the analysis are presented in Table 1. Mean sitting time (SD) was 6.60 (3.32) hours/day for the 1973–1978 cohort and 5.70 (3.04) hrs/day for the 1946–1951 cohort.

In the 1973–1978 cohort, sitting time was significantly higher in women who lived in urban areas, who were born in a non-English speaking country, or who reported that income management was impossible or difficult (Table 2). Women in full-time work and those in skilled occupations sat more, whereas those in full-time home duties or in blue collar occupations sat less, than women in the respective referent category. Women without caring duties (ie, did not provide care for adults or children) sat more than women with these duties. Sitting time was also significantly higher in women who reported studying or doing  $> 15$  hrs/wk of passive leisure, compared with women in the respective referent category. Health and health behavior variables were not associated with sitting time, except that sitting time was higher in those with sleeping problems and lower in current smokers, compared with the respective referent category.

In the 1946–1951 cohort, sitting time was significantly higher in women who were single, in urban women, and in women who reported that it was easy managing on their income (Table 3). In contrast with the younger cohort, mid-age women born in a non-English speaking country sat less than their Australian-born counterparts. As in the young women, sitting time was higher for mid-age women in full-time work and for those in skilled occupations, and lower for those in full-time home duties, without jobs, or in blue collar occupations, compared with women in the respective referent category. Compared with women with low education (no formal education or school certificate), women with a university education sat more and those with a trade/apprenticeship or a certificate/diploma sat less. As in the young women, mid-aged women who reported studying, or doing  $> 15$  hrs/wk of passive leisure sat more than women in the respective referent category. Women who reported

moderate or high PA levels or were nondrinkers sat less, while overweight and obese women, women with  $\geq 3$  chronic conditions, and smokers sat more, than women in the respective referent category.

## Discussion

This study provides initial evidence of the factors associated with sitting time in young and mid-age Australian women. A wide range of variables was correlated with sitting time, and although many of these are not easily modifiable, the results are useful for identifying groups of women who may benefit from targeted interventions to reduce sitting time and for identifying opportunities for intervention.

Most of the demographic and time-use variables that were significantly associated with sitting time were similar between the 2 age cohorts. Previous studies have shown that indicators of socioeconomic disadvantage, such as living in deprived neighborhoods,<sup>14,15</sup> low income,<sup>14–16</sup> no paid job,<sup>16,17</sup> and low education,<sup>16,17</sup> are associated with higher TV viewing time. In contrast, in the current study, indicators of socioeconomic advantage, such as full-time work and skilled occupations in both cohorts and university education in the mid-age cohort, were associated with high sitting time.

Two types of work—home duties and caring duties—however, were associated with lower sitting time. Young and mid-age women who worked full-time in home duties had relatively low sitting time and sitting time in the young women was lower for more children. Interestingly, sitting time was high in mid-age women who could easily manage on their income and in younger women who found it difficult to manage on their income. This may reflect the fact that many of these younger women, even those in full-time jobs requiring long hours of sitting, may be struggling to manage on their income, especially if they are establishing independent homes and repaying university fee loans. We conclude that relationships between socioeconomic position and sitting time in women reflect their paid work and unpaid family roles, with more highly educated full-time working women having a greater risk of high sitting time than women who are engaged in unpaid family caring duties.

Young and mid-aged women with sleeping problems reported higher sitting time. Lack of sleep may lead to an increase in sedentary behaviors due to tiredness, as has been hypothesized to be the case in children.<sup>31</sup> Overweight or obese mid-aged women sat more than those with a healthy weight, which is in line with recent suggestions that there may be a bidirectional or reverse relationship between sitting time and BMI in mid-aged people.<sup>32,33</sup> The higher sitting in mid-aged women with  $\geq 3$  chronic conditions could also reflect a bidirectional relationship, as sitting is a potential risk factor for chronic conditions,<sup>34</sup> but chronic conditions may also affect the ability to be physically active, thereby indirectly influencing sitting time.

**Table 2 Correlates of Sitting Time in Women Born Between 1973–1978<sup>a</sup>**

|   | Univariate (N = 7724)          |             |       | Multivariable (N = 7724)       |             |       |

<sup>a</sup> Data collected in 2003, except country of birth (1996) and alcohol intake (2000). <sup>b</sup> Very low ( $\leq 4800$  KJ), low ( $>4800-6000$  KJ), moderate ( $>6000-7100$  KJ), high ( $7100-8800$  KJ), and very high ( $>8800$  KJ). *Note. Italic* indicates the referent category. **Boldface** indicates significant difference in sitting time compared with the referent category for that variable.

**Table 3 Correlates of Sitting Time in Women Born Between 1946–1951<sup>a</sup>**

|  | Univariate (N = 8198)          |             |                | Multivariable (N = 8198)       |             |                |
|--|--------------------------------|-------------|----------------|--------------------------------|-------------|----------------|

<sup>a</sup> Data collected in 2003, except country of birth (1996) and education (1996).

<sup>b</sup> Having sleeping problems was associated with sitting time in the univariate analysis, which included all women who provided sitting time data (n = 10,308), but the variable was not significant (P = 0.09) in the smaller sample included in the multivariable analysis and whose data are shown here for both the univariate and multivariate models (n = 8198).

<sup>c</sup> None (<40 MET-min/week), very low (40 to <300 MET-min/week), low (300 to <600 MET-min/week), moderate (600 to <1200 MET-min/week), high (≥1200 MET-min/week). **Note.** *Italic* indicates the referent category. **Boldface** indicates significant difference in sitting time compared with the referent category for that variable.

In the mid-aged women, there was evidence of a cluster of healthy behaviors associated with lower sitting time: women with moderate or high activity levels and those who did not smoke or drink had lower sitting times. In contrast, smoking was associated with lower sitting time in the younger women. A potential explanation is that, in this age-group, smoking may be an indication of socioeconomic status, with women who smoke being less likely to be in full-time work, and in less skilled occupations. However, our analyses were adjusted for these variables.

It is not yet clear what amount of sitting time would be a meaningful difference in health risk,<sup>34</sup> and although statistically significant, some of the differences in sitting time among the different categories of some variables were small. We found the largest differences in average sitting time, 1 to 1.25 hours, for working hours, different occupations, and time spent in passive leisure in both age groups. Combinations of work and passive leisure resulted in even greater differences in sitting time. For example, full-time working mid-aged women in skilled occupations and engaging in > 15 hrs/week of passive leisure sat for 8.8 (SD 3.1) hrs/day (n = 158), whereas mid-aged women in professional occupations who did not work full-time and engaged 1 to 15 hrs/week in passive leisure sat only 4.9 (SD 2.8) hrs/day (n = 839). These findings suggest both occupational sitting and leisure-time sitting offer opportunities for intervention.

The major strength of this study was the use of large national samples of working age women. Because ALSWH addresses a myriad of variables that are important for women, we were able to include some unconventional variables that may be associated with sitting time. Moreover, because data from women at 2 contrasting life-stages were included in the analyses, we were able to examine potential age and generational differences in sitting-time correlates. The main limitation is the reliance on self-report data, which are vulnerable to bias and measurement error. Self-report data are, however, pragmatic for large population-based studies.<sup>35</sup> In addition, the reliability and validity of the sitting question has not been tested although it is similar to the IPAQ sitting question, which has been shown to have acceptable reliability and validity in women.<sup>23</sup>

In conclusion, young and mid-aged women who are in full-time work, in skilled occupations, and those who report high levels of passive leisure should be targeted in interventions to decrease sitting time. These findings suggest that interventions for reducing sitting time should focus on both occupational and leisure-time sitting.

### Acknowledgments

The Australian Longitudinal Study on Women's Health (ALSWH), which was conceived and developed by groups of interdisciplinary researchers at the Universities of Newcastle and Queensland, is funded by the Australian Government Department of Health and Ageing. The funding source had no involvement in the research presented in this paper. Dr. van

Uffelen and Dr. Heesch were supported by a NHMRC program grant (Owen, Bauman, and Brown; #301200) in Physical Activity and Health at The University of Queensland, School of Human Movement Studies. We thank Nelufa Begum, PhD, for her help with preparing the ALSWH datasets for the analyses presented in this manuscript.

<sup>a</sup> Data collected in 2003, except country of birth (1996) and alcohol intake (2000).

<sup>b</sup> Percentage may not add up to 100% due to rounding.

<sup>c</sup> P-values refer to differences in proportions between categories listed in the rows, using Pearson's chi square tests.

<sup>d</sup> None (<40 MET·min/week), very low (40 to <300 MET·min/week), low (300 to <600 MET·min/week), moderate (600 to <1200 MET·min/week), high (≥1200 MET·min/week).

<sup>e</sup> Very low (≤4800 KJ), low (>4800 to 6000 KJ), moderate (>6000 to 7100 KJ), high (7100 to 8800 KJ), and very high (>8800 KJ).

<sup>a</sup> Data collected in 2003, except country of birth (1996) and education (1996).

<sup>b</sup> Percentage may not add up to 100% due to rounding.

<sup>c</sup> *P*-values refer to differences in proportions between categories listed in the rows, using Pearson's chi square tests.

<sup>d</sup> None (<40 MET·min/week), very low (40 to 300 MET·min/week), low (>300 to <600 MET·min/week), moderate (600 to <1200 MET·min/week), high (≥1200 MET·min/week).

<sup>e</sup> Very low (≤4800 KJ), low (>4800 to 5800 KJ), moderate (>5800 to 6800 KJ), high (>6800 to 8300 KJ), and very high (>8300 KJ).
